

fsPHENIX Forward Tracking using PHGenFit and PHG4Hit

Jin Huang(BNL), Haiwang Yu (NMSU)

Jul 27, 2016

SpinFest2016 @ UC Riverside

Introduction

Motivation: Quickly produce fsPHENIX tracking performance with Geant simulation + Kalman Filter.

- More realistic than Sagitta calculation.
- Good estimation before the detector design finalized.
- Serves as prototype for forward sPHENIX tracking software
 - with future pattern recognition component.

Procedure:

- Simulation
 - \Rightarrow PHG4TruthInfoContainer.
 - \Rightarrow PHG4Hit.
 - \Rightarrow TGeo detector geometry in DST run node (PHGeometry by Jin)
- Feed the Kalman Filter:
 - PHG4Hit \Rightarrow Measurements: Smear PHG4Hit according to given detector resolution.
 - Measurements grouping: use MC truth information, "pseudo pattern recognition"
 - Seed: Smeared MC truth information

- ❖ Method Verification: test with 3-layer vacuum detector.
- ❖ Test using EIC concept FGEM, arXiv:1402.1209
- ❖ Companion with previous studies.
- ❖ Implementation of a forward tracking module based on this idea.

Method Verification: Using 3-layer vertical plane tracking

3-layer vertical plane testing setup

First, we tested the code using 3-layer vertical planes:

- The world and all detector material is G4_Galactic.
- 3-layer vertical planes with black holes outside.
- $\delta r = 1\text{cm}$
- $r\delta\phi = 100\ \mu\text{m}$

Vacuum, 3-layer, $\eta = 3.0$, $r\delta\phi = 100 \mu\text{m}$, $\delta r = 1\text{cm}$

PHGenFit results are very similar with the Geant4 Sagitta calculation:

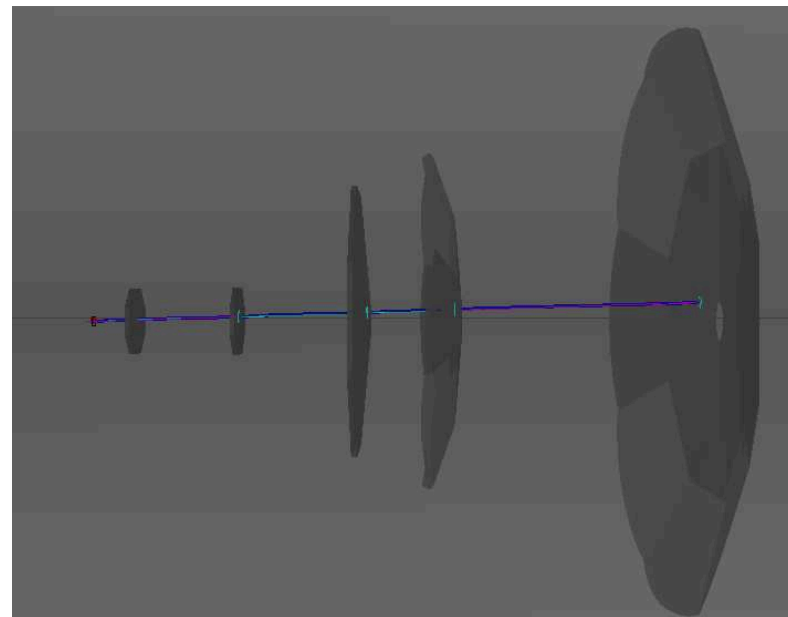

- Blue circle: $\sigma_{\text{Sagitta}}/\text{Sagitta}$ vs. p from Geant4 simulation
- Black dot: σ_p/p vs. p from PHGenFit Kalman fitting.

EIC Concept FGEM tracker:
Momentum resolution σ_p/p

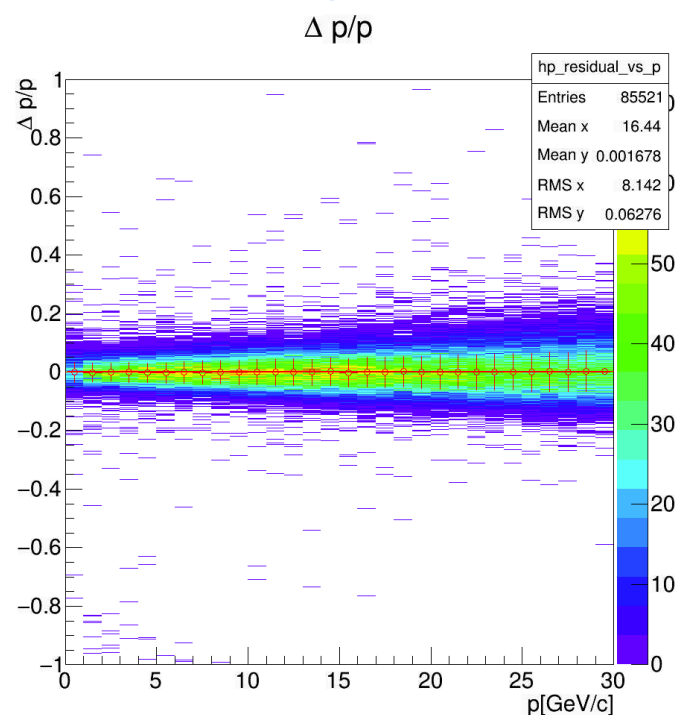

5(4)-station Forward GEM Detector

- Detector setup using G4_FGEM_fsPHENIX.C in sPHENIX master branch.
- $z = 17$ cm ($1.01 < \eta < 2.7$), 62 cm ($2.15 < \eta < 4.0$), 120, 160, 275 ($1.45 < \eta < 4$) cm
- $\delta r = 1$ cm, $r\delta\phi = 100 \mu\text{m}$ ($\eta = 1.5 \sim 2.5$) $50 \mu\text{m}$ ($\eta = 2.5 \sim 4$)
- sPHENIX field, no passive piston.
- **Tracking used vertex** from smeared truth vertex (0,0,0) and $50 \mu\text{m}$ resolution.

how to calculate σ_p/p

- 2D histo: $(p_{\text{Reco}} - p_{\text{True}})/p_{\text{True}}$ vs p_{True} , (right plot)
- For each slice of p_{True} , fit with Gaussian, extract mean as offset (Grey dots), sigma as momentum resolution (σ_p : Black dots), left plot.
- We also calculated $\langle \sigma_{\text{Sagitta}} / \text{Sagitta} \rangle$ as a reference (Blue circles): Sagitta is calculated using vertex, station at 120cm and station at 275 cm.

Result: σ_p/p for different pseudo-rapidity

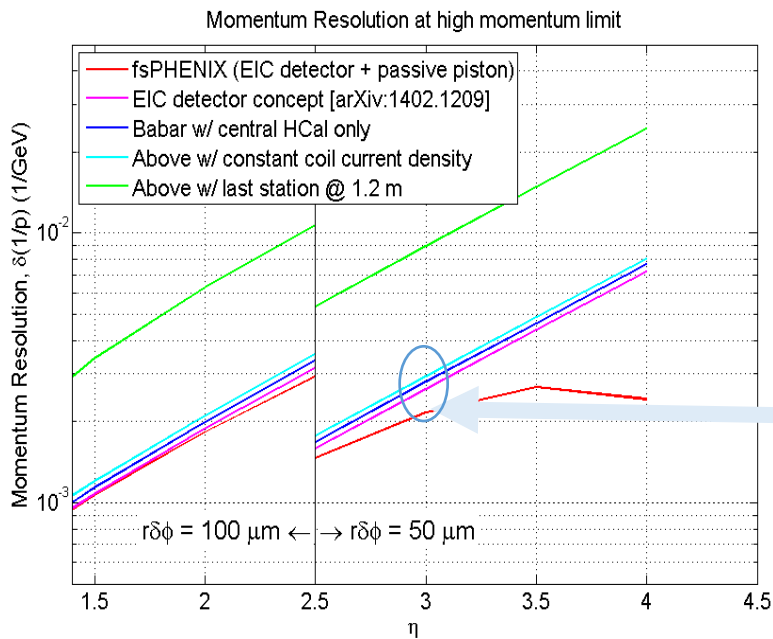

Details for each curve are in the backups.

PDF format: https://www.phenix.bnl.gov/WWW/p/draft/yuhw/fsPHENIX/FGEM_PHGenFit.pdf

Compare with previous studies

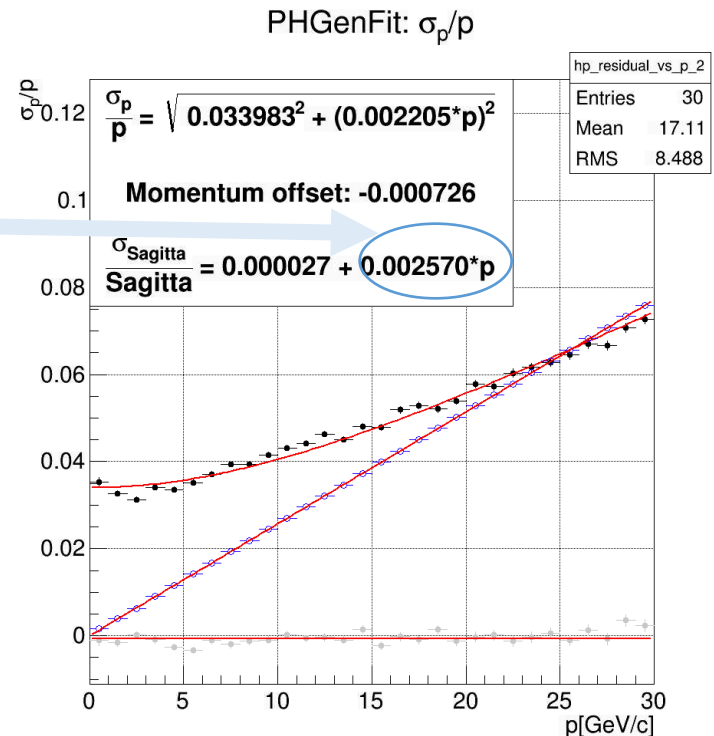

Compare with previous studies, Jin's MatLab calculation

Jin's calculation based on vertex + optimum Sagitta plane + 300cm last station.

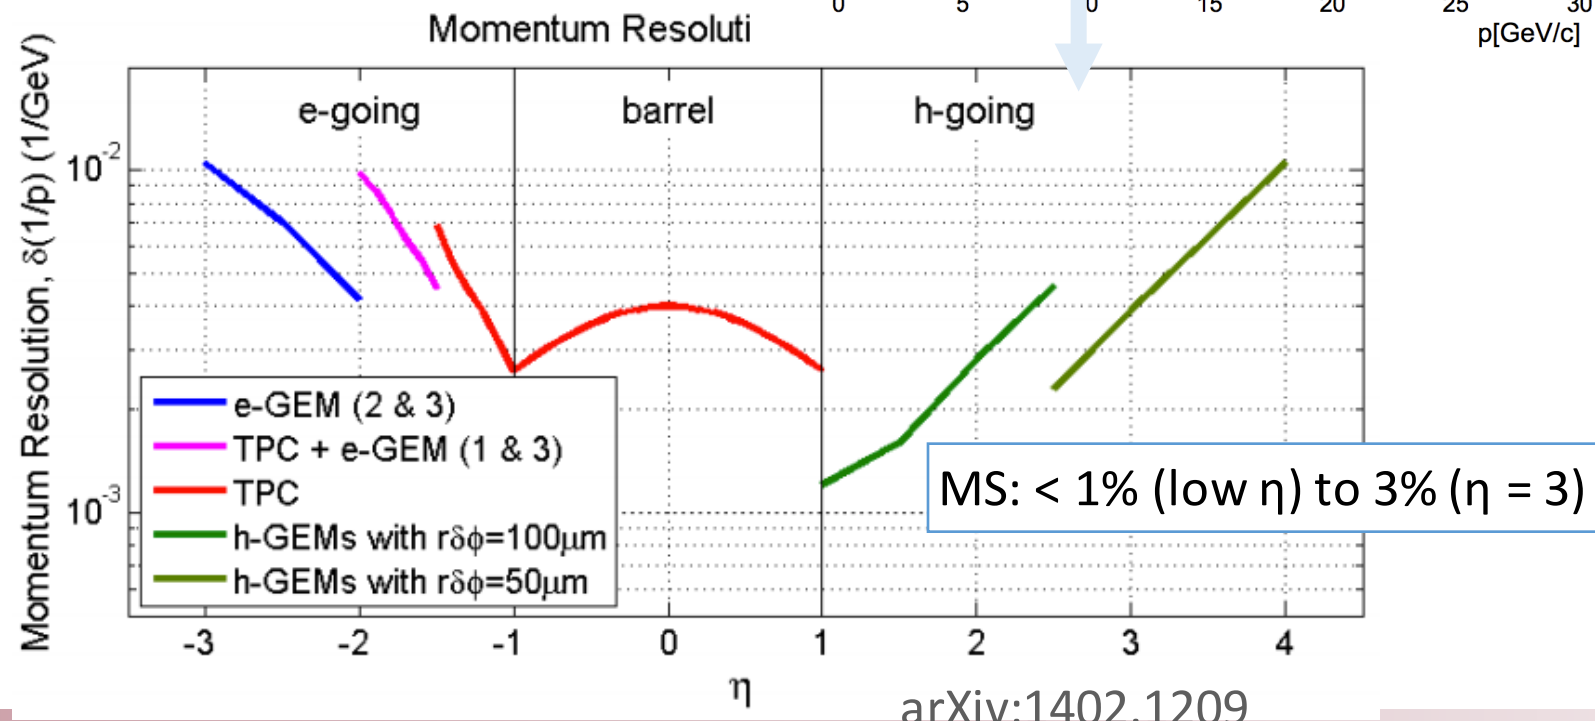

GenFit fitting for $\eta = 3.0$, corresponding to **magenta curve** in left plot.

- The linear term, p1, from the σ_S/S is **consistent with left plot**, both are $\sim 0.25\%$.
- The p1 term from full GenFit Kalman is better than σ_S/S . That could be caused by that we have more stations in full Kalman.

Compare with previous studies, arXiv:1402.1209

- Linear term p1 is better than previous Sagitta tracking study by **using a vertex in the fitting**.
- Constant term p0, (Multiple Scattering Effect) is constant with previous Sagitta tracking study.

arXiv:1402.1209

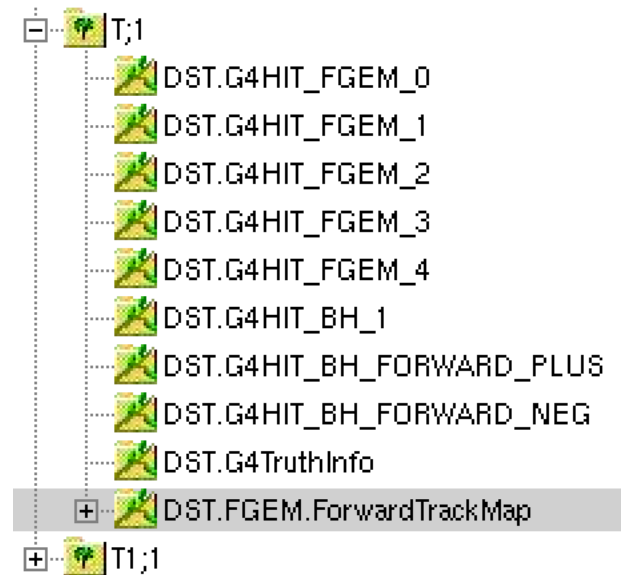

A forward tracking module based on this idea:
ForwardTracking

ForwardTracking module

- In sPHENIX git - analysis: [analysis/ForwardTracking](#)
- Measurements: PHG4Hits + smearing
 - Smear PHG4Hits according to given detector resolution
 - No detector digitization and cellularization.
- Pseudo pattern recognition using Monte Carlo truth information
 - "track_id" matching between PHG4Hits and PHG4Particle in PHG4TruthInfoContainer
 - With manually input hit finding efficiency and noisy finding probability
- The TGeo geometry required by GenFit is provide by Jin's PHG4Geometry machineries.
- Output node: a SvtxTrackMap "FGEM/ForwardTrackMap"

Using this module

```
void FGEM_Reco(int verbosity = 0) {  
  
    //-----  
    // Load libraries  
    //-----  
  
    gSystem->Load("libfun4all.so");  
    gSystem->Load("libForwardTracking.so");  
  
    //-----  
    // Fun4All server  
    //-----  
  
    Fun4AllServer *se = Fun4AllServer::instance();  
  
    PHG4HitKalmanFitter* kalman = new PHG4HitKalmanFitter("PHG4HitKalmanFitter");  
  
    kalman->set_mag_field_file_name("/phenix/upgrades/decadal/fieldmaps/fsPHENIX.2d.root");  
    kalman->set_FGEM_phi_resolution(50E-4);  
    kalman->set_FGEM_r_resolution(1.);  
    kalman->set_pat_rec_hit_finding_eff(1.);  
    kalman->set_pat_rec_nosise_prob(0.);  
    kalman->set_do_evt_display(false);  
  
    se->registerSubsystem(kalman);  
}
```

First look at the output

TGeo used by GenFit in the DST RUN node

Summary

- The idea of GenFit Kalman Filter with smeared G4 PHG4Hits tested. Results consistent with previous studies.
- An forward tracking module implemented based on this idea. Under testing.

Next:

- Test and make sure every thing is working as expected.
- Output some evaluation NTuples.
- Simulations with physics motivations!

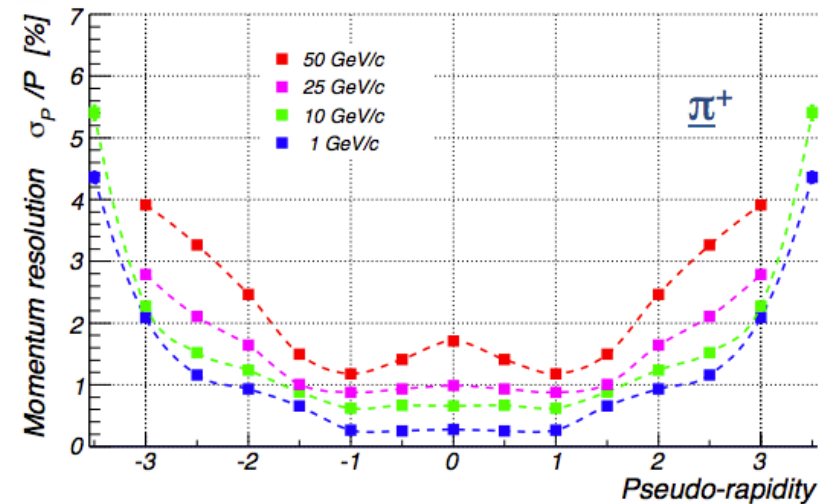

Backups:

Compare with BeAST:

- Resolution is about x2 of the BeAST, despite BeAST use x2 stronger magnetic field + silicon tracker, as we used a much longer tracking arm.
- Our higher momentum resolution could be improved by also switching GEM to high precision silicon tracker.
