

## P06 X-ray analysis of the magnetar SGR 1900+14 with NuSTAR and XMM-Newton

*Monday, 19 November 2018 17:20 (1 minute)*

“Magnetars are pulsars with extremely strong magnetic fields  $10^{14-15}$  G and thought to be powered by dissipation of their magnetic energies. The mechanism of converting their magnetic energies to the X-ray radiations is still a mystery, so that X-ray observations of magnetars are very important.

We observed one of the famous magnetars SGR 1900+14 with NuSTAR and XMM-Newton simultaneously on 2016 October. In the timing analysis, we found the rotation period on 2016 October was 5.2267(1) s and the period derivative fluctuated more than 50 % in these 20 years. We also discovered the shape of pulse profiles changes at  $\sim 10$  keV. In the spectral analysis, we determined the hard-tail photon index very precisely,  $\Gamma = 1.13(8)$ , and also discovered the photon index varies depending on the rotation phase. Furthermore, we discuss the potentiality of HXMT to target SGR 1900+14, making full use of its broad-band observation up to 250 keV.”
