Nuclear magic numbers correspond to fully occupied energy shells of protons or neutrons inside atomic nuclei. Doubly magic nuclei, with magic numbers for both protons and neutrons, are spherical and extremely rare across the nuclear landscape. Although the sequence of magic numbers is well established for stable nuclei, experimental evidence has revealed modifications for nuclei with a large asymmetry between proton and neutron numbers. Here we provide a spectroscopic study of the doubly magic nucleus ^{78}Ni , which contains fourteen neutrons more than the heaviest stable nickel isotope. We provide direct evidence of its doubly magic nature, which is also predicted by *ab initio* calculations based on chiral effective-field theory interactions and the quasi-particle random-phase approximation. Our results also indicate the breakdown of the neutron magic number 50 and proton magic number 28 beyond this stronghold, caused by a competing deformed structure. State-of-the-art phenomenological shell-model calculations reproduce this shape coexistence, predicting a rapid transition from spherical to deformed ground states, with ^{78}Ni as the turning point.

Outline of this work

- First spectroscopy on ^{78}Ni has been performed at RIBF, RIKEN.
- Excited states of ^{78}Ni were obtained by combination of the two key detectors; DALI2 γ -ray spectrometer and MINOS liquid hydrogen system.
- Doubly shell-closure of ^{78}Ni has been confirmed.
- At the same time, emergence of shape-coexistence nature in ^{78}Ni has been suggested, resulting in the possible quenching of neutron- and proton-shell gaps beyond this anchor point.

Nucleus: a quantum many-body system

- A picture of nuclear structure: nucleons in single particle states
- Large gaps at 2, 8, 20, 28, 50, \dots , reproduced by a spin-orbit interaction in a Woods-Saxon type potential
- **Magic numbers** are the numbers of proton and neutron at shell-closure
- 28, 50,.. are the numbers induced by spin-orbit splittings

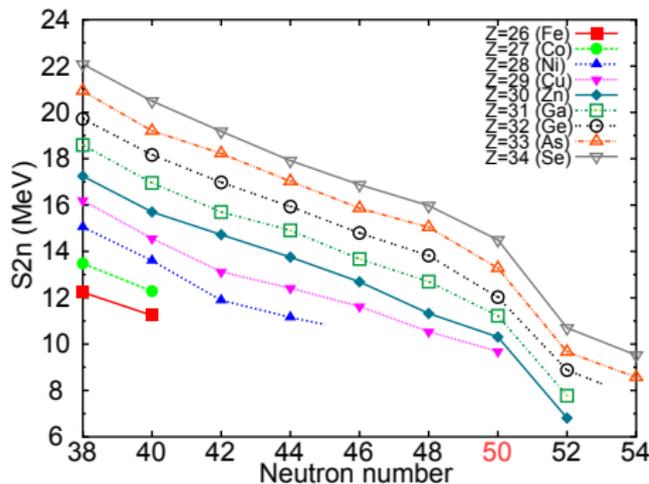

How to determine the shell closures?

- Systematic trend of **mass difference** is a direct indication of the ground state property.
- Two-neutron separation energy, S_{2n} , are shown. Sudden drops above **$N = 50$ gap** are evident.
- It's hard to reach exotic region.

How to determine the shell closures?

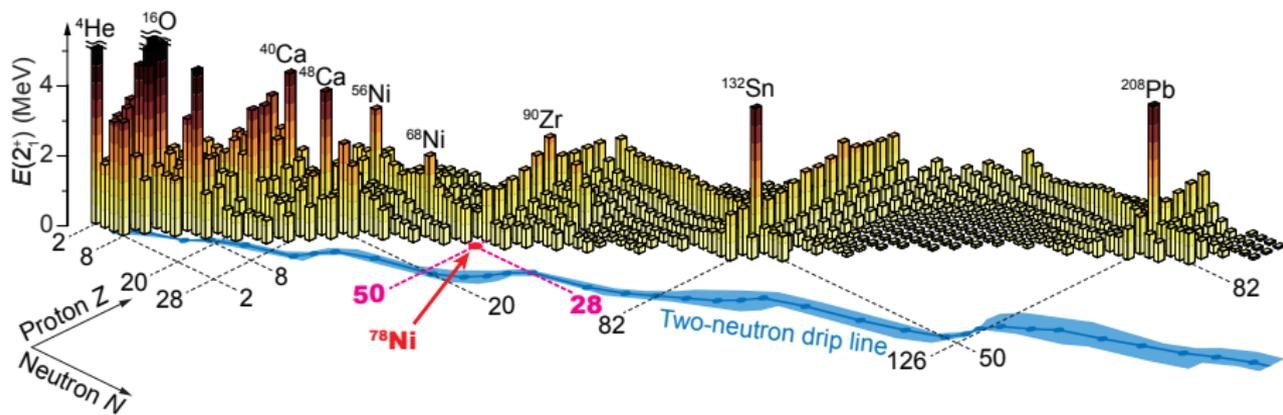

- Systematic trend of **mass difference** is a direct indication of the ground state property.
- Two-neutron separation energy, S_{2n} , are shown. Sudden drops above **$N = 50$ gap** are evident.
- It's hard to reach exotic region.

- Instead, the **excitation energy** works as a good indicator of shell closure and single particle energies.
- The energy of **first 2^+ state** of even-even nuclei is rather commonly used for a first clue of shell-closure.

$E(2_1^+)$ systematics among the nuclear chart

- The energy $E(2^+)$ is a good indicator of the shell closure.
- ^{78}Ni is the only candidate of the unobserved neutron-rich particle-bound doubly magic nuclei.
- **Aim of this work:** First γ -ray spectroscopy of doubly magic ^{78}Ni .

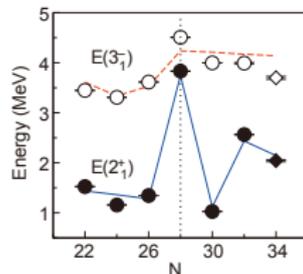

(Evaluation of the drip line from J. Erler *et al.*, Nature **486**, 509-512 (2012))

“Magic numbers” are not universal

Emergence of a new magic numbers

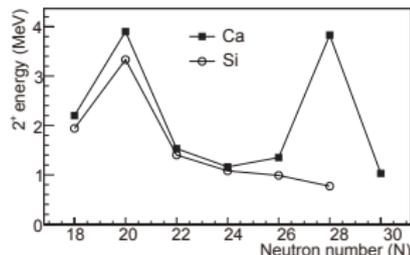

Appearance of shell-closure along calcium isotopes in $^{52,54}\text{Ca}$ was confirmed by high excitation energies $E(2^+)$. This indicates new magic numbers: $N = 32, 34$.

(Figure from D. Steppenbeck *et al.*, Nature **502**, 207-210 (2013))

Disappearance of magic number

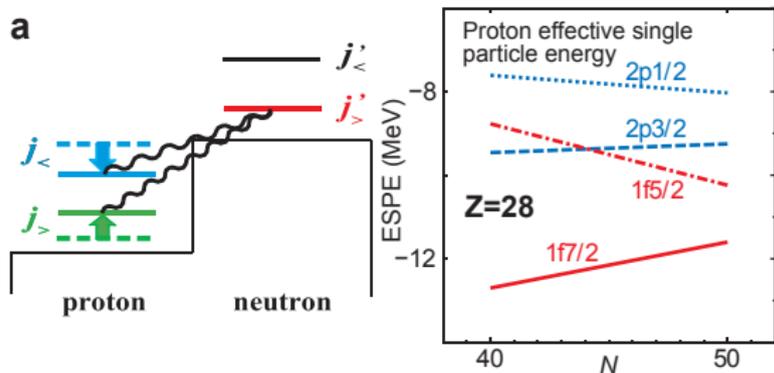

Low excitation energy of ^{42}Si indicates the $N = 28$ shell closure has been collapsed in much less proton nuclei.

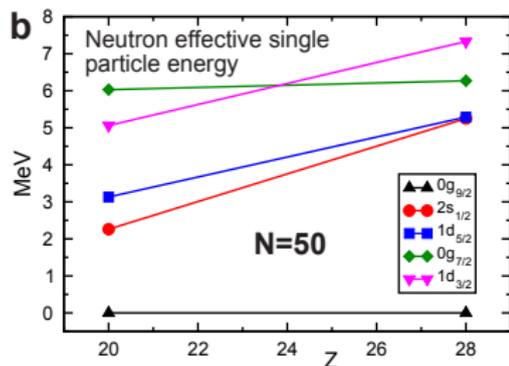

(Figure from B. Bastin *et al.*, Phys. Rev. Lett. **99**, 022503 (2007))

What is the driving force of the “rearrangement”?

- Tensor term was pointed out as a major reason for modifying these shell gaps. It works between protons and neutrons as reducing the spin-orbit splitting.
- Toward ^{78}Ni , the $Z = 28$ gap are expected to be reduced by filling neutrons in $g_{9/2}$ shell up to $N = 50$.
- While, the $N = 50$ gap is assumed to be collapsed in less proton nuclei $Z < 28$, below ^{78}Ni .

Two-step reaction to populate excited states of ^{78}Ni

- Primary ^{238}U with 345 MeV/u at an average intensity of **13 p nA**
- Secondary beam from in-flight fission of ^{238}U collected by BigRIPS
- A secondary target and a γ -ray spectrometer were installed in the midst of magnetic spectrometers, F8
- $^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$ and $^{80}\text{Zn}(p, 3p)^{78}\text{Ni}$ reactions

$B\rho - \Delta E$ -TOF method applied for PID

Observations

- Velocity β : Deduced from TOF (Time of flight)

$$\beta = \frac{L}{c} \cdot \frac{1}{TOF}$$

- Atomic number Z : Deduced from β and energy loss ΔE

$$-\frac{dE}{dx} = \frac{4\pi}{m_e c^2} \cdot \frac{Z^2}{\beta^2} \cdot \left(\frac{e^2}{4\pi\epsilon_0}\right)^2 \cdot n \left[\ln \left(\frac{2m_e c^2 \beta^2}{I(1-\beta^2)} \right) - \beta^2 \right]$$

- Mass-to-charge ratio A/Q : From β and magnetic rigidity $B\rho$

$$\gamma m \frac{v^2}{\rho} = QvB, \quad B\rho = \frac{\gamma m v}{Q} = \frac{\beta \gamma c m_u}{e} \cdot \frac{A}{Q}$$

Beamline detectors for particle identification

Detectors

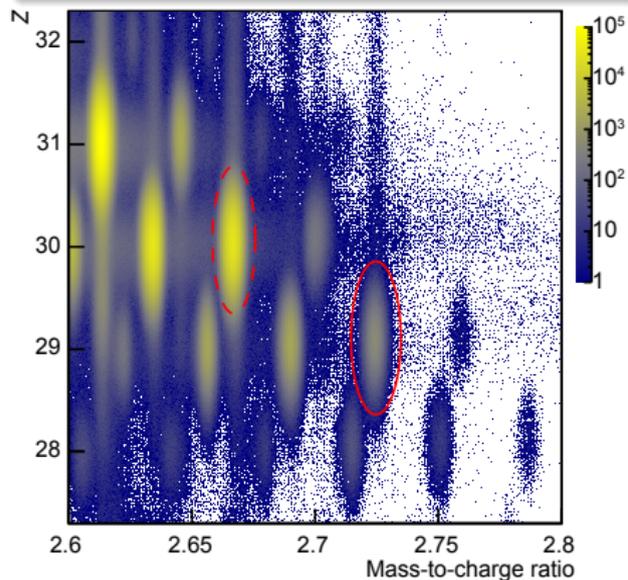

- TOF: Timings between **plastic scintillators**
location: both ends of each spectrometer (F3, F7, F8, and F11)
- ΔE : Energy loss was obtained by **MUSIC** (multi-sampling ionization chamber)
location: end of each spectrometer (F7 and F11)
- $B\rho$: Positions and angles were obtained by **PPAC** (position-sensitive Parallel Plate Avalanche Counters)
location: dispersive (F5, F9) and achromatic (F3, F7, F8, and F11) foci

Obtained particle identification plots

PID in upstream (BigRIPS)

^{79}Cu : 5.2 particles/s

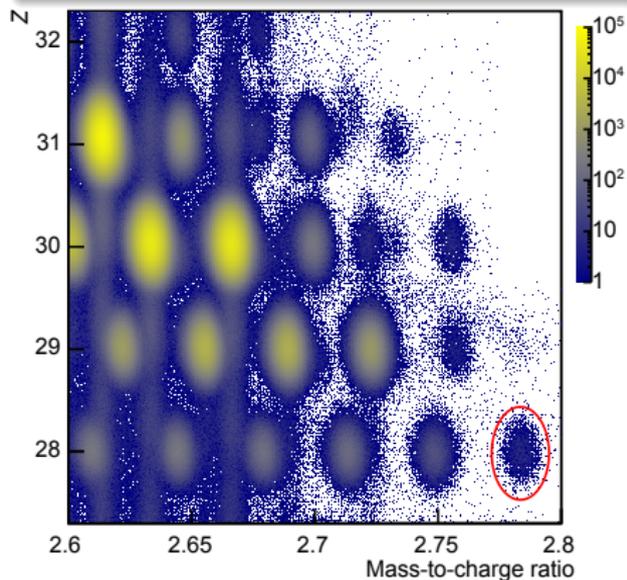

^{80}Zn : 290 particles/s

PID in downstream (ZeroDegree)

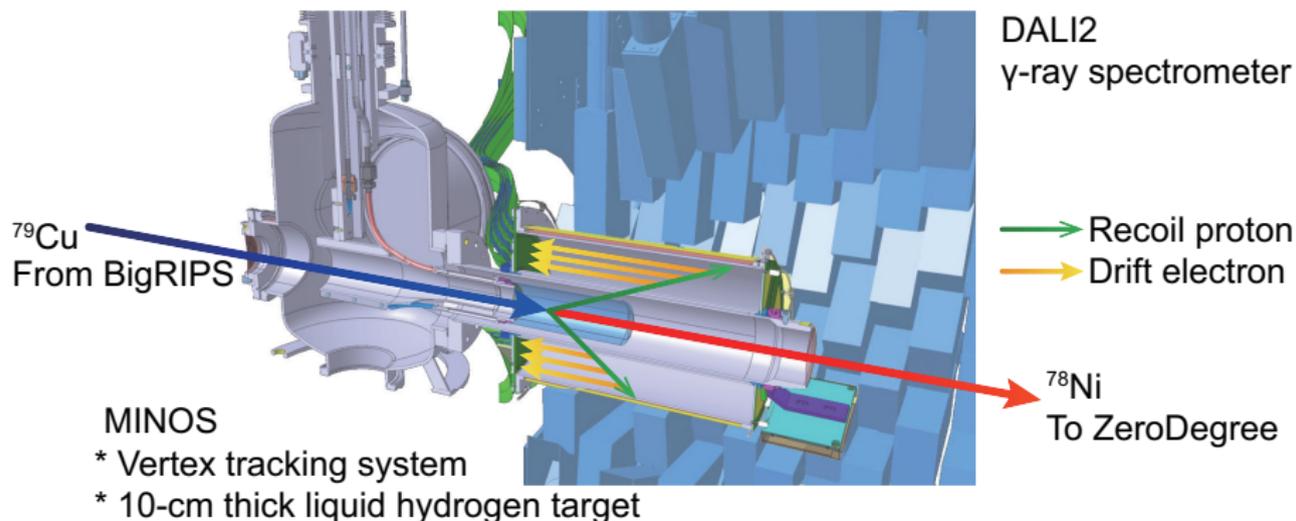

$^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$: 937 evts

$^{80}\text{Zn}(p, 3p)^{78}\text{Ni}$: 815 evts

Secondary reaction target and γ -ray detector array

- **Thick liquid hydrogen target (MINOS)**: Tracks of the recoil protons were obtained to reconstruct the reaction vertices. $\Delta x \sim 5$ mm.
- **High-efficiency scintillator array (DALI2)**: Intrinsic resolution and efficiency were 10% and 20% for 1 MeV γ -ray from moving system.

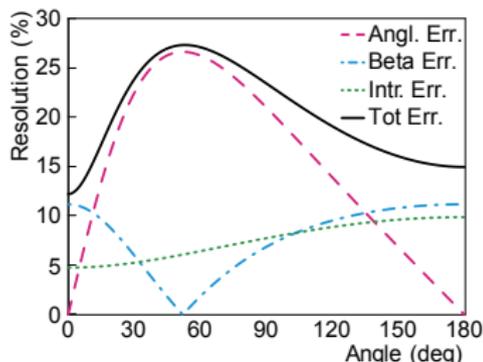

Doppler broadening in in-beam γ -ray spectroscopy

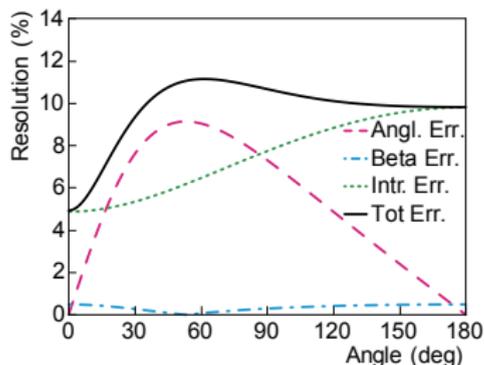

Uncertainty of the γ -ray energy from **Doppler broadening** should be taken into account to gain the luminosity by employing thick secondary target.

$$\frac{E_\gamma}{E_{\gamma_0}} = \frac{\sqrt{1 - \beta^2}}{1 - \beta \cos \theta_\gamma}, \quad \delta_{\text{tot.}}^2 = \left(\frac{\Delta E_{\gamma_0}}{E_{\gamma_0}} \right)^2 = \delta_\theta^2 + \delta_\beta^2 + \delta_{\text{intr.}}^2.$$

Different γ -ray populations in respective reactions

While a strong γ -ray population at 2600 keV can be seen in the $(p, 2p)$ reaction, another 2900-keV transition is observed in the $(p, 3p)$ channel.

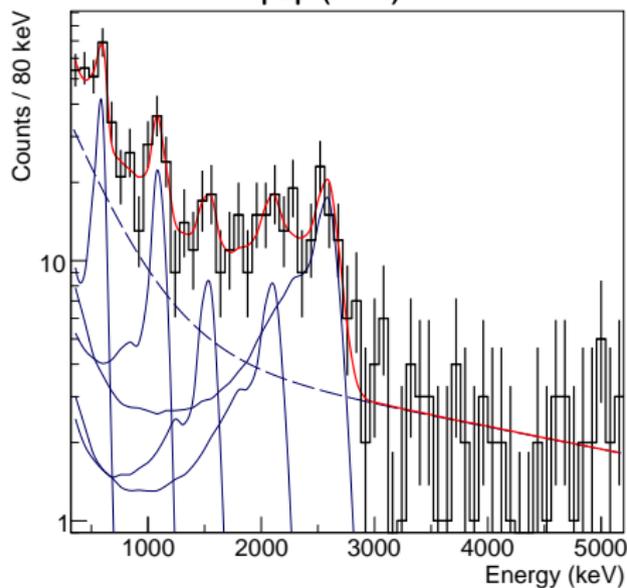

Strategy for analyzing the γ -ray spectra of respective reaction channels

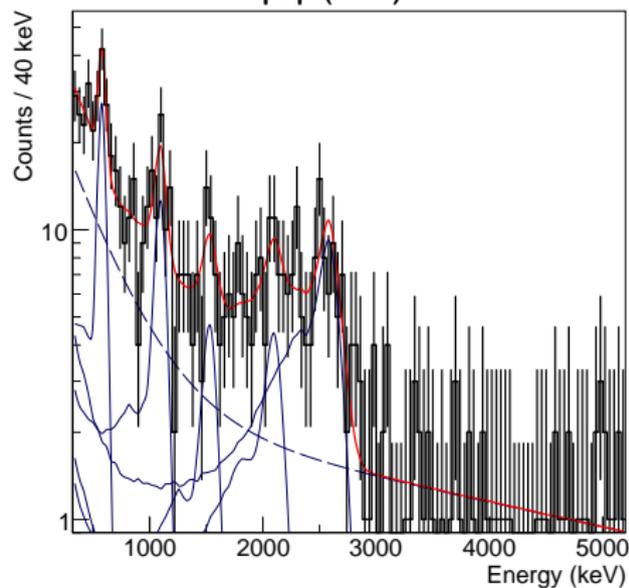

- Analyze spectrum of each reaction channel, $(p, 2p)$ and $(p, 3p)$, individually.
- Energy determination of the peaks: maximum likelihood, using multi-dimensional probability function.
- Significance levels: p -test deduced by likelihood-ratio.
- Reconstruction of energy levels: intensity relationship and γ - γ analysis.

The $^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$ channel

Spectrum with 80 keV binning
p2p (m<6)

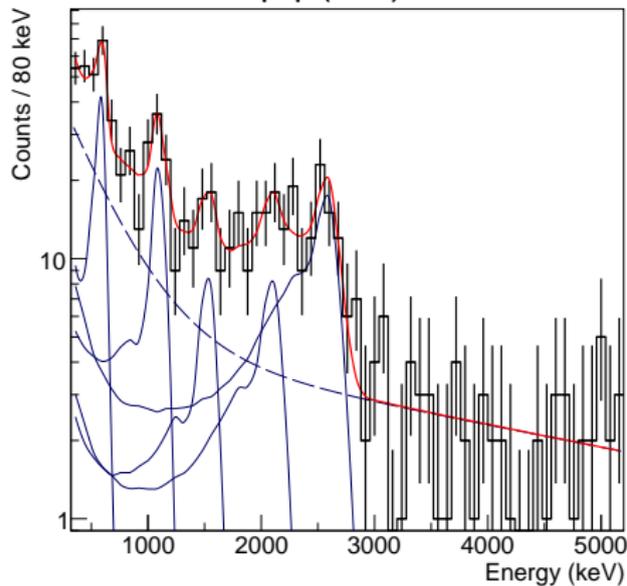

Spectrum with 40 keV binning
p2p (m<6)

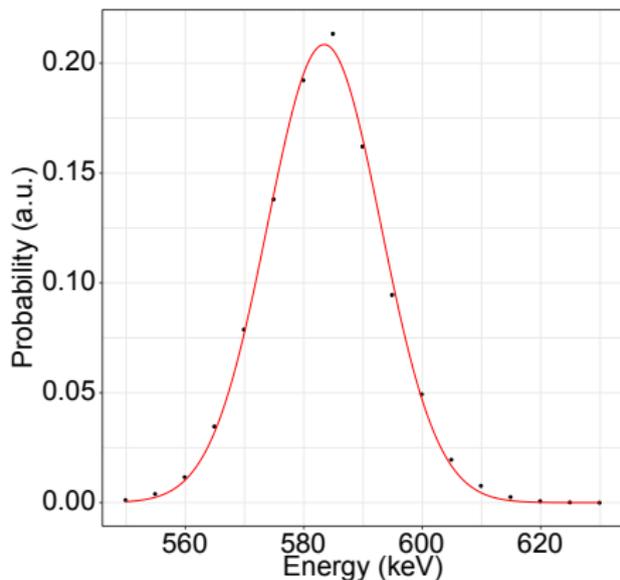

The $^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$ channel

Spectrum with 80 keV binning
p2p ($m < 6$)

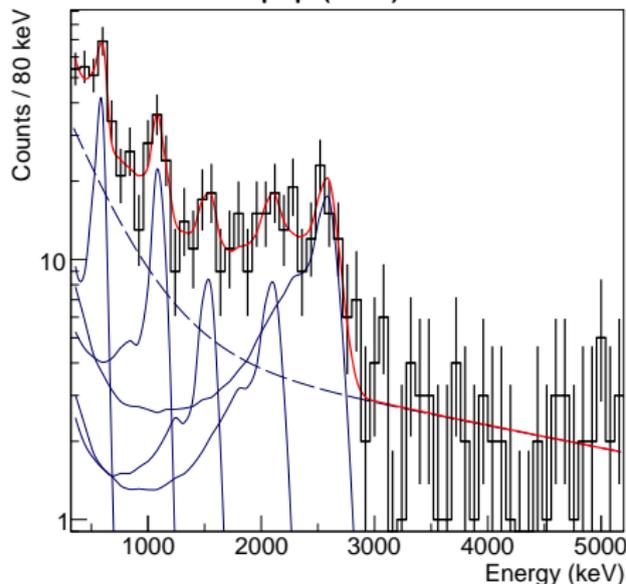

- Maximum likelihood with 5 response functions and a double-exponential function

The $^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$ channel

Spectrum with 80 keV binning
p2p ($m < 6$)

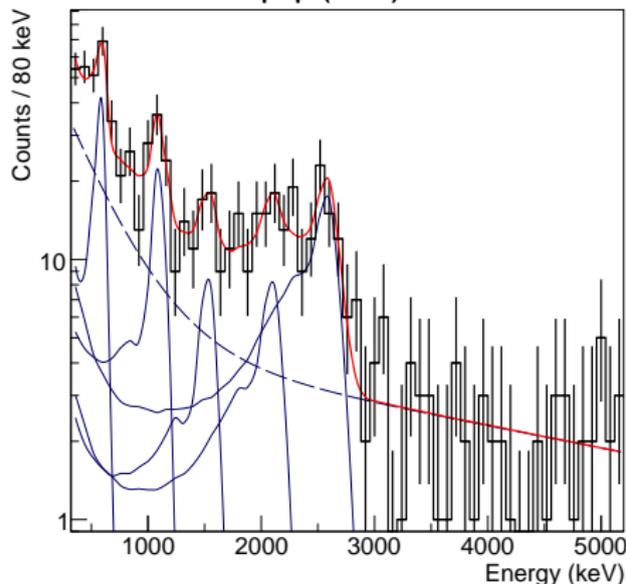

- Result with 1 s.d. error of E_γ and relative intensity I_{rel}
- Significance levels were deduced from p -test

E_γ (keV)	I_{rel} (%)	S. L.
583(10)	49(11)	5.3
1103(14)	49(12)	4.3
1540(25)	28(11)	2.6
2110(48)	33(13)	2.9
2600(33)	100(15)	7.5

The $^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$ channel

Spectrum with 80 keV binning
p2p ($m < 6$)

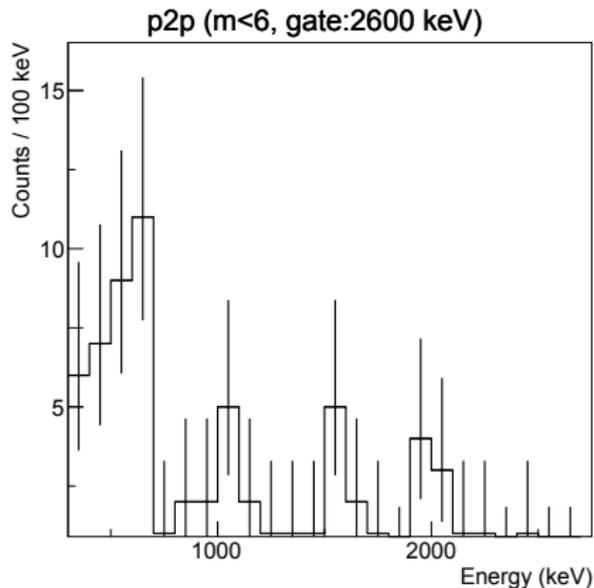

- Result with 1 s.d. error of E_γ and relative intensity I_{rel}
- Significance levels were deduced from p -test

E_γ (keV)	I_{rel} (%)	S. L.
583(10)	49(11)	5.3
1103(14)	49(12)	4.3
1540(25)	28(11)	2.6
2110(48)	33(13)	2.9
2600(33)	100(15)	7.5
2910(43)	—	1.2

γ - γ coincidence analysis

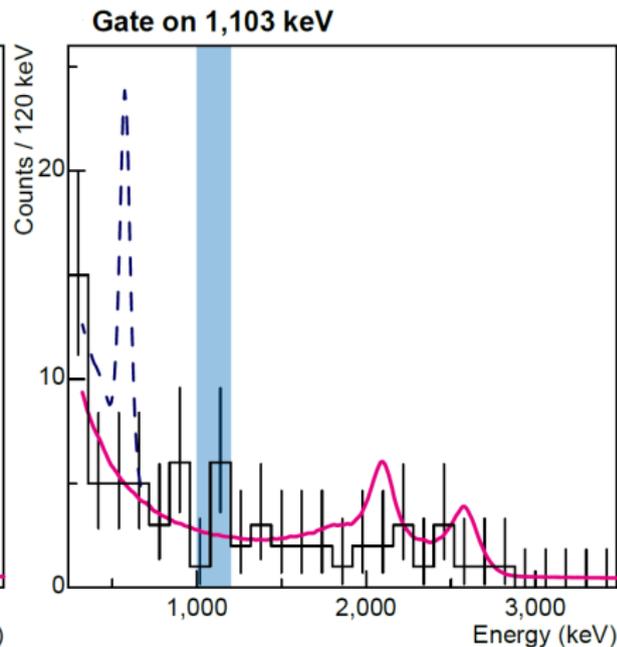

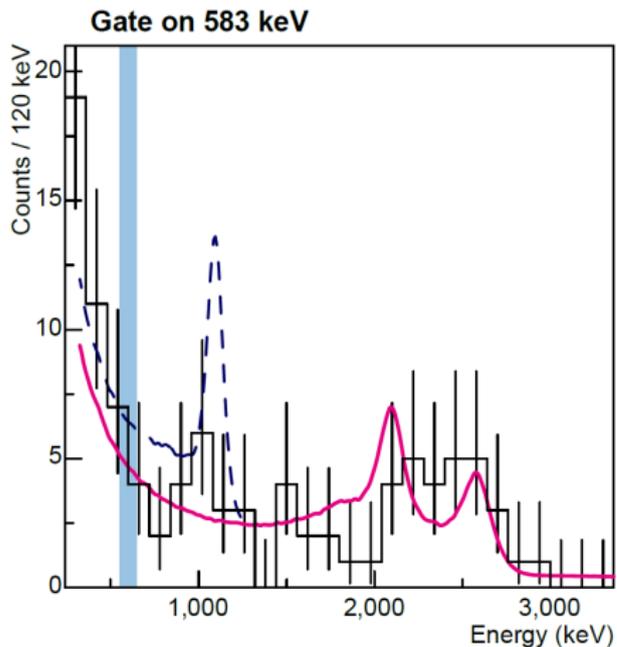

All low-lying transitions are feeding the 2600 keV state

- γ - γ coincidence spectrum after gating with 2600 keV transition
- All four low-lying states are in coincidence.
- No background events were subtracted

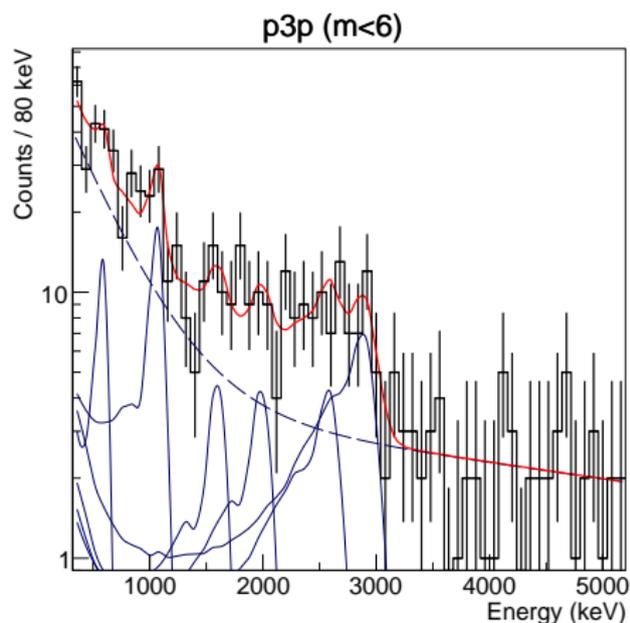

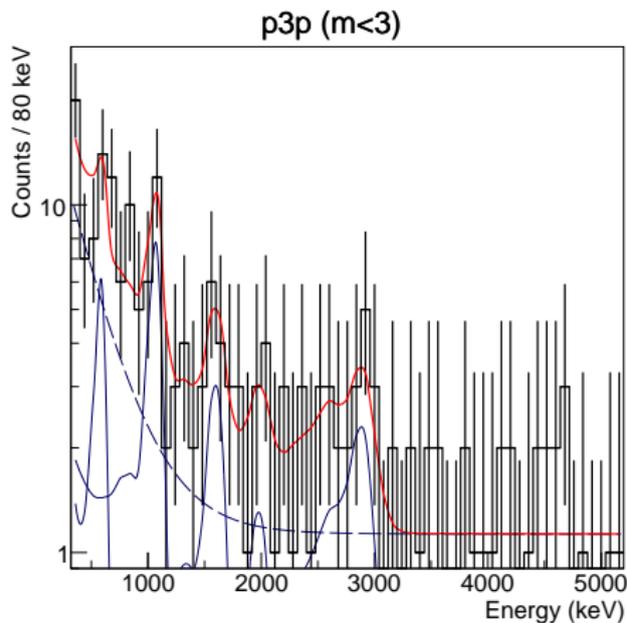

γ - γ coincidence analysis

No coincidence between 583 keV and 1103 keV

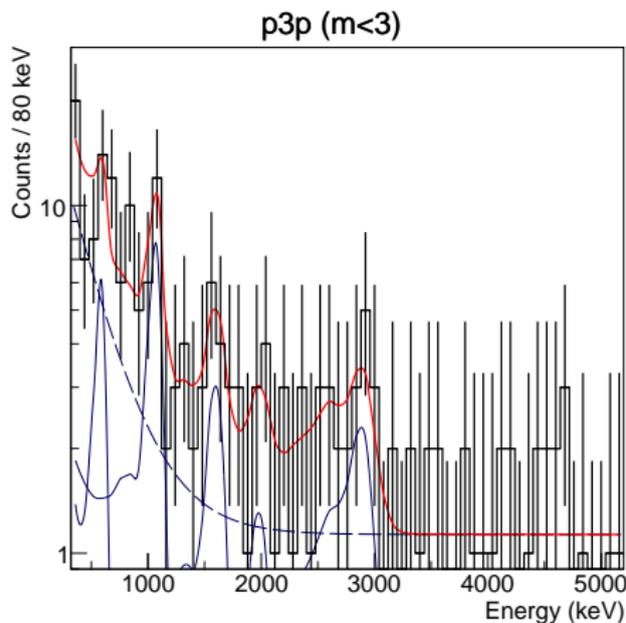

The $^{80}\text{Zn}(p, 3p)^{78}\text{Ni}$ channel

High lying transition at 2900 keV

The $^{80}\text{Zn}(p, 3p)^{78}\text{Ni}$ channel

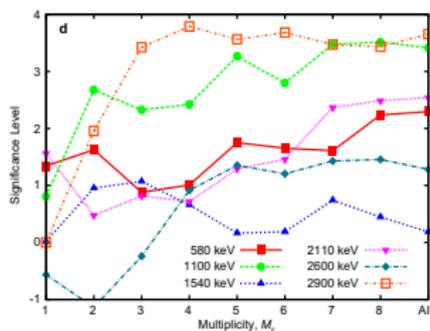

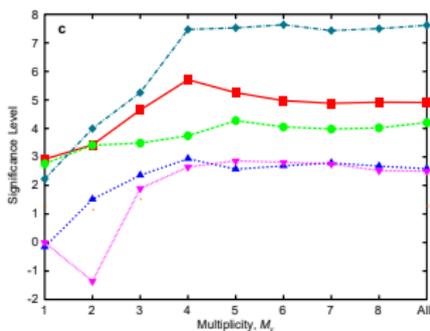

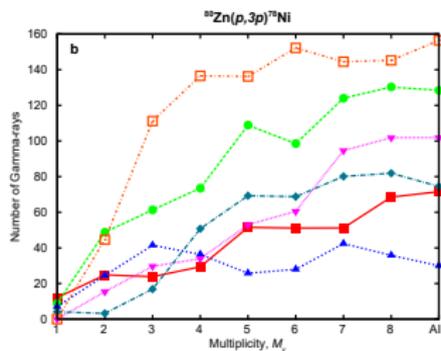

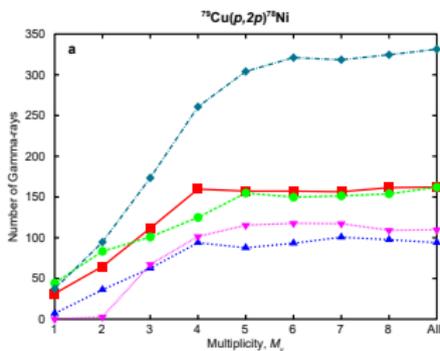

High lying transition at 2900 keV

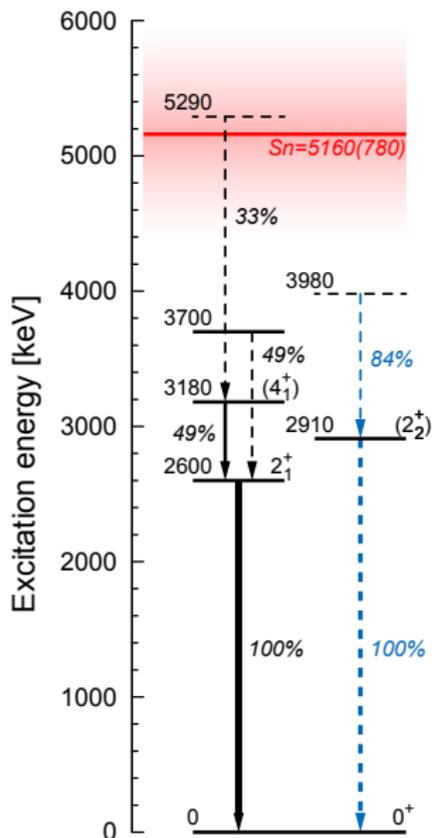

- A transition at 2910(43) keV was found, which was not seen in the $(p, 2p)$ reaction
- Enhancement at lower γ -ray multiplicity condition and the large intensity are seen

E_γ (keV)	I_{rel} (%)	S. L.
581(16)	46(19)	1.8
1067(17)	84(26)	3.5
2710(200)	48(30)	1.4
2910(43)	100(29)	3.7

Evolution of I_{rel} and significance levels with γ -ray multiplicity

Obtained level scheme of ^{78}Ni

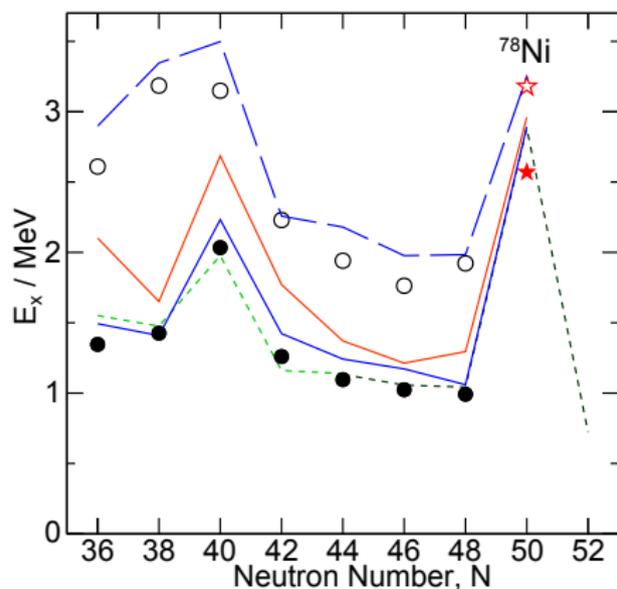

- Black and blue transitions were observed in the $(p, 2p)$ and $(p, 3p)$ reactions, respectively.
- Solid line: Significance level $\geq 5\sigma$
- The most strong transitions at 2600 keV and 2900 keV in respective reactions are tentatively assigned as 2^+ states feeding the ground state directly.
- The state at 3180 keV is tentatively assigned as 4^+ state.

The unit of the excitation energy, E_x , of each state is MeV.

Reaction selectivity for collective states

This is still an open question:

- The spectroscopic factor for the $(p, 2p)$ and two-nucleon amplitude for the $(p, 3p)$ in the calculations prefers populating spherical states rather than deformed states.
- No theory for explaining the mechanism of the $(p, 3p)$ reaction is available.

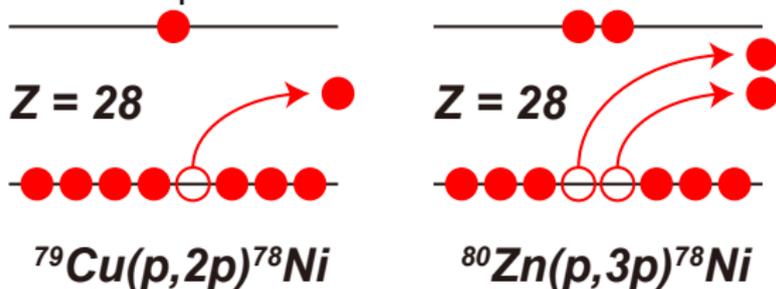

Reaction selectivity for collective states

This is still an open question:

- The spectroscopic factor for the $(p, 2p)$ and two-nucleon amplitude for the $(p, 3p)$ in the calculations prefers populating spherical states rather than deformed states.
- No theory for explaining the mechanism of the $(p, 3p)$ reaction is available.

In a naive picture...

- In $1p$ knockout reaction, $1p-1h$ (particle-hole) may be favored.
- While, the final state of $2p$ removal reaction may be more connected to $2p-2h$ and more particle-hole excitations.

Low inclusive cross sections of ^{78}Ni

- The reaction cross sections (inclusive cross sections, σ_{incl}) were also investigated.
- The cross section to produce ^{78}Ni were found as almost **4 times lower** than other isotones.

Reaction		σ_{incl} (mb)
$^{79}\text{Cu} \rightarrow ^{78}\text{Ni}$	-1p	1.7(4)
$^{80}\text{Zn} \rightarrow ^{79}\text{Cu}$	-1p	8.0(3)
$^{81}\text{Ga} \rightarrow ^{80}\text{Zn}$	-1p	5.2(3)
$^{82}\text{Ge} \rightarrow ^{81}\text{Ga}$	-1p	7.5(9)
$^{80}\text{Zn} \rightarrow ^{78}\text{Ni}$	-2p	0.016(6)
$^{81}\text{Ga} \rightarrow ^{79}\text{Cu}$	-2p	0.061(5)
$^{82}\text{Ge} \rightarrow ^{80}\text{Zn}$	-2p	0.067(8)

Quasi-free ($p, 2p$) reaction theory

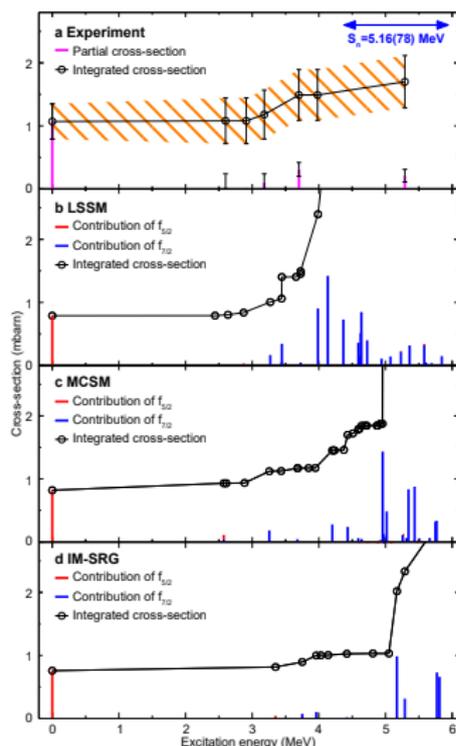

- DWIA (distorted-wave impulse approximation) calculation (K.Ogata) for $^{79}\text{Cu}(p, 2p)^{78}\text{Ni}$ reaction[1].
- Reproduced well for the reaction cross section of neutron-rich oxygen isotopes with shell-model calculations with SFO interaction in p and sd shells[2].
- Product of spectroscopic factor C^2S from shell-model and single-particle cross section σ_{sp} as below:

$$\sigma_{\text{th}}(j, \alpha) = C^2S(j, \alpha) \cdot \sigma_{\text{sp}}(j, S(\alpha))$$

[1] T. Wakasa *et al.*, Prog. Part. Nucl. Phys. **96**, 31-87 (2017)

[2] S. Kawase *et al.*, Prog. Theor. Exp. Phys. **2018**, 021D01 (2018)

Most final states after the reaction may be unbound

- Evolutions of running sum (black line) in experiment and theory are in consistent up to 5 MeV.
- Most strength above neutron separation energy S_n in MCSM.
- Confirmed the understanding of the $(p, 2p)$ reaction with the DWIA calculation

Table of Contents

- 5 Discussion
- 6 Conclusion and outlook**

Conclusion and outlook

Conclusion of this work

- Strong γ -ray transition at 2600(33) keV was confirmed as the first excitation state.
- The agreement with several calculations showed the **doubly magic nature in ^{78}Ni**
- A finding of second 2^+ state at 2910(43) keV in the $(p, 3p)$ reaction suggested the **shape coexistence in ^{78}Ni**

Conclusion and outlook

Conclusion of this work

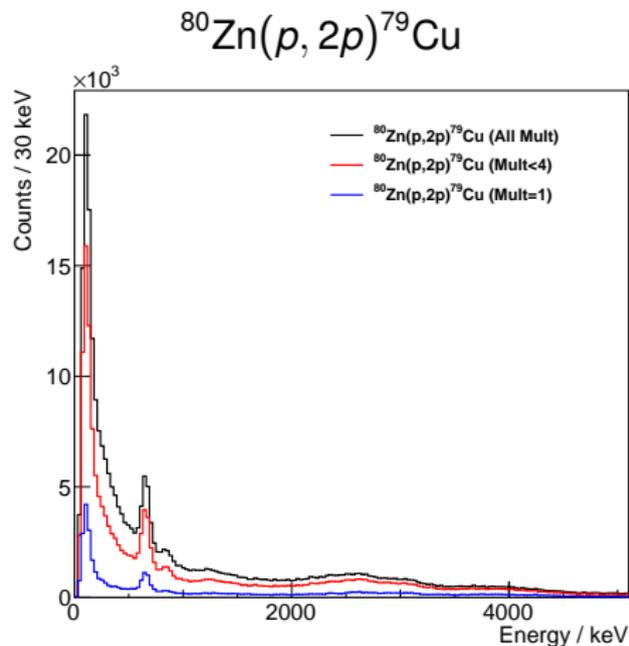

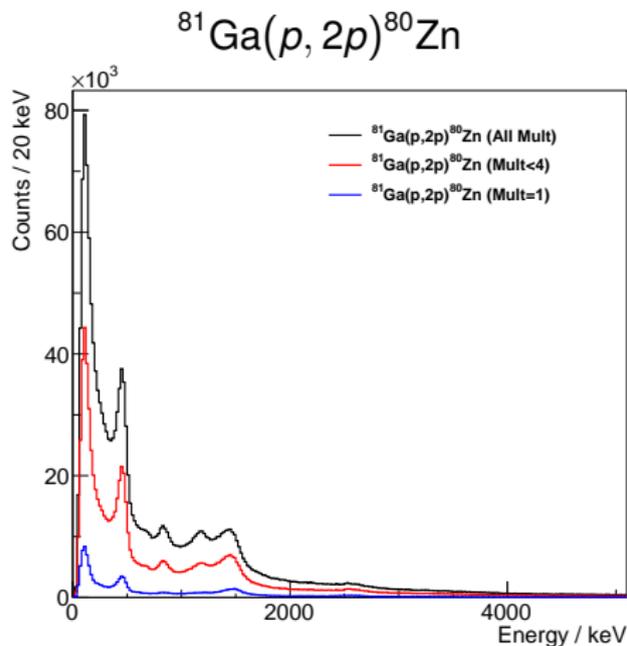

- Strong γ -ray transition at 2600(33) keV was confirmed as the first excitation state.
- The agreement with several calculations showed the **doubly magic nature in ^{78}Ni**
- A finding of second 2^+ state at 2910(43) keV in the $(p, 3p)$ reaction suggested the **shape coexistence in ^{78}Ni**

Future outlook

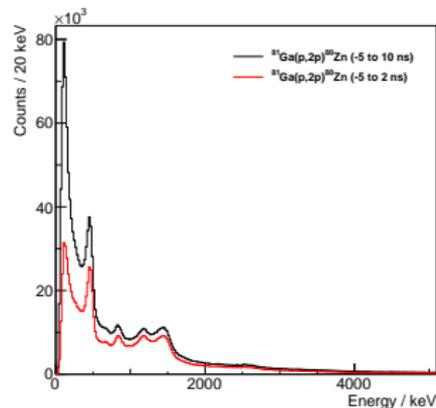

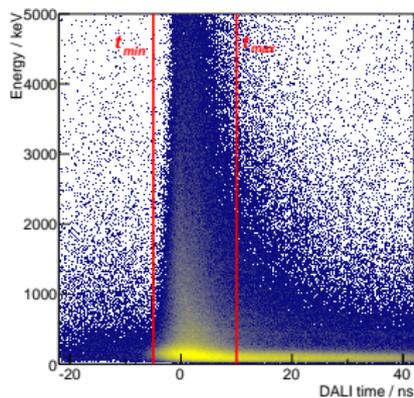

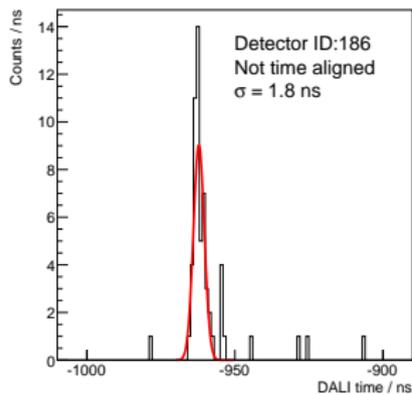

- Spectroscopic measurement beyond ^{78}Ni is desired.
- To investigate the shape coexistence, the measurement of 0_2^+ state in ^{78}Ni should also be considered.
- The development of the understandings of the reaction mechanism for the $(p, 3p)$ is also desired.
