# True XY Distributions for Polarized UPC\_AN+0.2

Slide 2

Position distribution is spherical as expected for small  $r < 2.0$  cm. But the more  $r$  tends towards 4 cm, the true xy distribution starts to respond to the square shape of our ZDC acceptance.

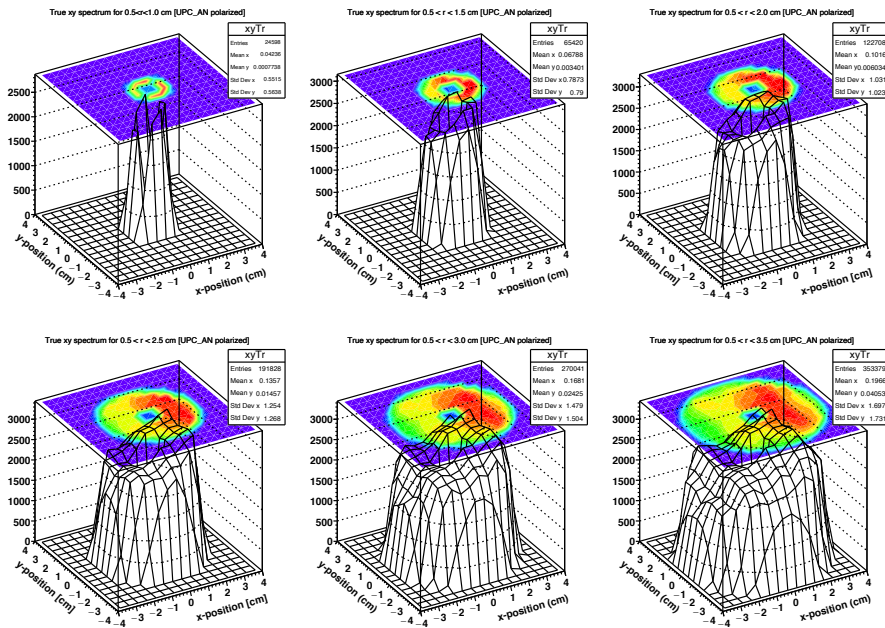

# True XY Distributions for Polarized UPC\_AN+0.2

Slide 3

According to my calculation so far, position distribution being spherical for small  $r < 2.0$  cm is meaningful for unsmeared 100 GeV neutrons peaking around 0.1 GeV/c according to:

$Pt(\text{true}) = r \cdot E_n(\text{true}) / IP$ , where  $IP = 1856$  cm for pAu, run15 data.

Therefore,  $r = Pt(\text{true}) * IP / E_n(\text{true}) = 0.1 \text{ (GeV/c)} * 1856 \text{ (cm)} / 100 \text{ GeV} = 1.856 \text{ cm} < 2.0 \text{ cm}$ .

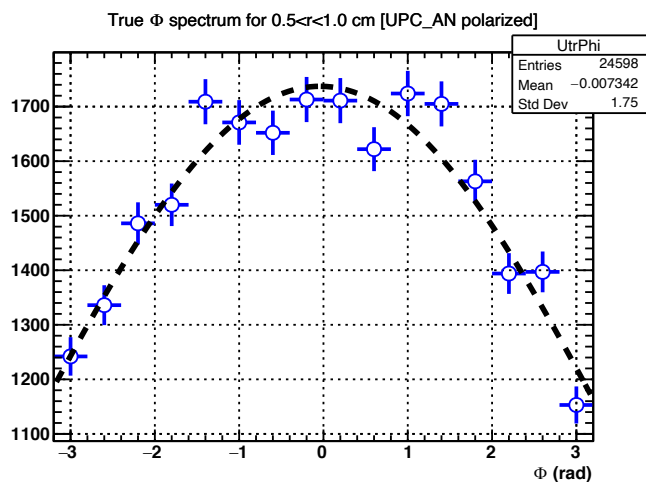

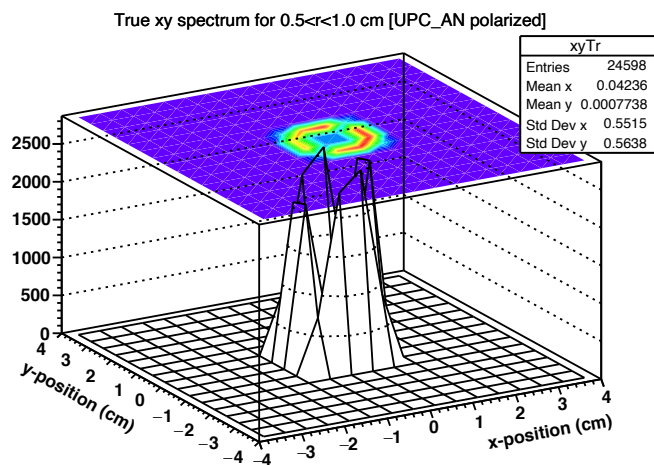

- But as we get passed  $r = 2$  cm going towards  $r < 4$  cm, which is the cut applied to data and, therefore, should be applied to the reconstructed and true spectra, the true xy position spectrum starts to take the square shape of our ZDC acceptance.
- So I am asking myself many questions like: I know the true beam is spherical but if it is projected on a 4 cm by 4 cm square x and y plane, would the true beam still remain completely spherical even close to 4cm or start to take the square shape like H<sub>2</sub>O does depending on container?

What effect can this square shape in our true position at  $r < 4$  cm have on our final results and so on? I have searched previous studies to see if I can come across true xy plot with  $r < 4$  cm but none so far.

# True XY and $\Phi$ Spectra for Various Radial Regions

Slide 4

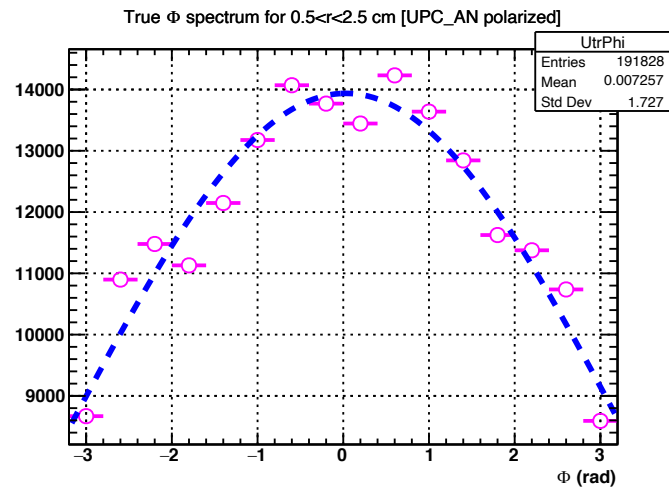

**Radial Regions:** Between 0.5 cm and 1.0 cm (left panels), 0.5 cm and 1.5 cm (right panels)

Slide 13

True azimuthal ( $\Phi$ ) distribution (Magenta) and reconstructed azimuthal distribution (blue)

**BACKUP**

# True and Reco XY and Phi

Slide 1

For the true:

- Maximum energy,  $E(\text{true}) = 100 \text{ GeV}$
- Transverse momentum peak,  $P_t(\text{peak}) = 0.1 \text{ GeV}$

From above information, true r cut is:

$P_t(\text{peak}) = [ r * E(\text{true}) ] / IP$ , where  $IP = 1856 \text{ cm}$  [ pAu run15 data ]

Therefore, r cut to the true is:

$r(\text{true}) = [ P_t(\text{peak}) * IP ] / E(\text{true}) = ( 0.1 * 1856 ) / 100 = \underline{1.856 \text{ cm} < 2.0 \text{ cm}}$

So applying  $r(\text{true}) < 4.0 \text{ cm}$  I applied in the first report while I was in BNL introduced some smearing.

True xy and phi distributions for neutrons are extracted from Lorentz math using the true variables  $x[\text{ipart}]$ ,  $y[\text{ipart}]$ ,  $z[\text{ipart}]$ ,  $px[\text{ipart}]$ ,  $py[\text{ipart}]$ ,  $pz[\text{ipart}]$ ,  $pdg$ ,  $pid = 2112$ , mass (M) and energy (E)

- Mass (M)

Extracted using method: `TDatabasePDG::Instance()->GetParticle(pdg)->Mass()`, where `pdg = TDatabasePDG::Instance()->ConvertGeant3ToPdg(pid[ipart])`

- Energy ( E )

Extracted using:

$E(\text{true}) = TMath::Sqrt(px[\text{ipart}]^2 + py[\text{ipart}]^2 + pz[\text{ipart}]^2 + mass^2)$

- Using `TLorentzVector`, true variables  $x$ ,  $y$ ,  $z$ ,  $px$ ,  $py$ ,  $pz$ ,  $E$ ,  $m$  are set using the method: `SetPxPyPzE( px[ipart], py[ipart], -pz[ipart], E)` and `SetXYZM(x[ipart], y[ipart], z[ipart], M)`

# True and Reco XY and Phi

Slide 2

From SetXYZM(x[ipart], y[ipart], 0., M) = L1, the true radial distance is:  
 $r(\text{true}) = \text{TMath::Sqrt}(L1.X() * L1.X() + L1.Y() * L1.Y())$  from which  
 $r_{\text{true}}(\text{min}) < 0.5 \text{ cm}$  due to SMD position resolution  
 $r_{\text{true}}(\text{max}) < 2.0 \text{ cm}$  as shown on top of previous slide.

And from SetPxPyPzE(px[ipart], py[ipart], -pz[ipart], E) = L2;  
True azimuthal distribution is,  $\text{Phi} = L2.\text{Phi}()$   
with azimuthal area divided into 16 azimuthal bins.

For the reconstructed xy distribution, reconstructed variables are used:  
 $xx_{\text{ev}}$  and  $yy_{\text{ev}}$  from which reconstructed radial distance is:  
 $r(\text{reco}) = \text{Sqrt}(xx_{\text{ev}} * xx_{\text{ev}} + yy_{\text{ev}} * yy_{\text{ev}})$  with;  
 $r_{\text{min}}(\text{reco}) > 0.5 \text{ cm}$  due to 1 cm position resolution of SMD  
 $r_{\text{max}}(\text{reco}) > 2.0 \text{ cm}$  for neutrons with  $Pt > 0.10 \text{ GeV}/c$  smeared neutrons.

The corresponding reconstructed phi distribution is calculated as:

$\text{Phi}(\text{reco}) = \text{TMath::ATan2}(yy_{\text{ev}}, xx_{\text{ev}})$

With  $xx_{\text{ev}}$  and  $yy_{\text{ev}}$  being reconstructed x and y position of neutrons respectively.
